IN THE CLAIMS

Please amend the claims to read as follows:

<u>Listing of Claims</u>

Claims 1-8 (Canceled).

9. (New) A radio base station apparatus comprising: a reception weight calculator that performs a weight calculation to determine a plurality of reception weights;

an adaptive array antenna receiver that performs an adaptive array antenna reception of signals from a plurality of communication terminals using a plurality of directional patterns formed based on the plurality of reception weights; and

a path searcher that combines power addition values respectively corresponding to the plurality of directional patterns of the signals received by the adaptive array antenna reception to determine a power combination value, creates a delay profile based on the power combination value, and performs a finger assignment using the delay profile to output a despreading timing used in the weight calculation for the adaptive array antenna reception.

10. (New) A radio base station apparatus comprising:

a reception weight calculator that divides a plurality of communication terminals into a plurality of groups and performs a weight calculation to determine a plurality of reception weights respectively corresponding to the plurality of groups;

an adaptive array antenna receiver that performs an adaptive array antenna reception of signals from the plurality of communication terminals using a plurality of directional patterns respectively corresponding to the plurality of groups formed based on the plurality of reception weights; and

a path searcher that combines power addition values respectively corresponding to the plurality of directional patterns of the signals received by the adaptive array antenna reception to determine a power combination value, creates a delay profile based on the power combination value, and performs a finger assignment using the delay profile to output a despreading timing used in the weight calculation for the adaptive array antenna reception.

11. (New) The radio base station apparatus according to claim 9, further comprising a threshold value decider that makes a threshold value decision on the power addition values, wherein the path searcher determines the power combination value from the power addition values after the threshold value decision.

- 12. (New) The radio base station apparatus according to claim 9, wherein the path searcher performs a following finger assignment using signals received by the adaptive array antenna reception with the plurality of reception weights respectively corresponding to the plurality of groups determined at the despreading timing.
- 13. (New) A radio communication method comprising the steps of:

dividing a plurality of communication terminals into a plurality of groups and performing a weight calculation to determine a plurality of reception weights respectively corresponding to the plurality of groups;

performing an adaptive array antenna reception of signals from the plurality of communication terminals using a plurality of directional patterns respectively corresponding to the plurality of groups formed based on the plurality of reception weights; and

combining power addition values respectively corresponding to the plurality of directional patterns of the signals received by the adaptive array antenna reception to determine a power combination value, creating a delay profile based on the power combination value, and performing a finger assignment using the

delay profile to output a despreading timing used in the weight calculation for the adaptive array antenna reception.
